

GRASP Patterns (Ch. 18)

- ❖ Responsibility:
 - “A contract or obligation of a type or class”
- ❖ Two type of responsibilities
 - knowing
 - ◆ about private encapsulated data
 - ◆ things that can derive or calculate
 - doing
 - ◆ something itself
 - ◆ initiating action in other objects

1

Responsibilities & Interactions

- ❖ Methods Implement Responsibilities

```

classDiagram
    class Sale {
        print()
    }
    class SalesLineItem {
        print()
    }
    Sale "1" --> "1*" SalesLineItem : [for each] sli := next
    Sale --> SalesLineItem : 2: print()
    
```

2

Patterns

- ❖ Named “problem/solution” pairs
- ❖ Primitive examples from OOP:
 - Model - View - Controller (MVC)
 - Object - Attribute - Value (OAV)
- ❖ GRASP (Larman)
- ❖ Gang of Four (GoF; Gamma, et. al.)

3

Basic GRASP Patterns

- ❖ Expert
- ❖ Creator
- ❖ Controller
- ❖ High Cohesion
- ❖ Low Coupling
- ❖ Learn the other patterns after these are mastered

4

Expert Pattern

- ❖ The most commonly used pattern
- ❖ Assign a responsibility to the information expert
 - the class that has the information necessary to fulfill the responsibility
- ❖ Example:
 - In POST, who should know the grand total of a sale?

5

Grand Total Expert?

```

classDiagram
    class Sale {
        date
        time
    }
    class SalesLineItem {
        quantity
    }
    class ProductSpecification {
        description
        price
        UPC
    }
    Sale "1" --> "1*" SalesLineItem : Contain
    SalesLineItem "1*" --> "1" ProductSpecification : Described by
    
```

- ❖ Who knows about *SalesLineItems* and their totals?

Answer: *Sale*

6

What Else is Needed?

- ❖ What constitutes the line item subtotal?
 - SalesLineItem.quantity
 - ProductSpecification.price
- ❖ Who is the expert on both of these?
 - Answer: SalesLineItem
- ❖ Sale needs to see subtotal msgs from SalesLineItem

7

Resulting Collaboration Diagram

- ❖ Sale needs to send subtotal msgs to each SalesLineItem and sum the results
- ❖ In turn, SalesLineItem must send a price msg to ProductSpecification

8

Resulting Design

9

Expert - Conclusions

- ❖ In the real world, items don't tell you their price; line items don't tell you their total
 - But in O-O world, they do!
 - This principle is called "Animation" or the "Do it Myself" principle
- ❖ Also works in the workplace (real world)
 - Who puts together the profit/loss statement?
 - Ans: the person in accounting with all the data

10

Creator Pattern

- ❖ Assign class B the responsibility to create an instance of class A if one of the following is true:
 - B aggregates A-type objects (collects)
 - B contains A-type objects (owns)
 - B records instances of A-type objects
 - B closely uses A-type objects
 - B is an expert w/r/t creating A-type objects
 - ♦ B has the initializing data that will be passed to A when it is created
- ❖ In all cases, B is the creator of A-type objects!

11

Who Should Create SalesLineItem Instances?

- ❖ Answer: Sale - since it aggregates many SalesLineItem instances
- ❖ Requires a makeLineItem method be defined in Sale

12

Resulting Design

```

classDiagram
    class Sale {
        date
        time
        makeLineItem()
    }
    class SalesLineItem {
        :SalesLineItem
    }
    Sale --> SalesLineItem : create(quantity)
    
```

❖ Question: Who would best be able to create a Payment object?
 – Answer: *Sale* - since it aggregates necessary data (like total sale) to generate the object.

13

Low Coupling Pattern

- ❖ Formalized by Constantine & Yourdon
 – *Structured Design, 1974*
- ❖ *Coupling* is the degree to which modules (separate functions or methods) are inter-related.
- ❖ Low coupling is desired
- ❖ Levels of coupling are identified

14

Levels of Coupling / Cohesion

❖ Data - Low	Best	❖ Informational - High
❖ Stamp		❖ Functional
❖ Control		❖ Sequential
❖ Common		❖ Communication
❖ Content - High		❖ Temporal
		❖ Logical
		❖ Coincidental - Low
	Worst	

15

Data Coupling

- ❖ The lowest level of coupling (the best form)
- ❖ Also, the most common form of coupling
- ❖ Passing parameters between modules as data
- ❖ The fewer parameters passed, the lower the coupling
- ❖ Return values are used as data in the caller

16

Stamp Coupling

- ❖ Selected global variables are shared by multiple modules or routines
- ❖ If unexpected values arise in these globals, who is responsible?!
 – Requires a “watch” feature of a symbolic debugger to get a handle on who’s responsible
- ❖ Use of global variables is discouraged when parameter passing would suffice

17

Control Coupling

- ❖ Involves passing of control flags (either through parameters or global variables) as data between modules.
- ❖ The return value of the function determines the flow of control in the calling module
 – if (func()) then ... else ...
- ❖ What if there’s an error in func()?!?

18

Common Coupling

- ❖ Modules are dependent on one another (bound together) by global data blocks
- ❖ Fortran common blocks are the reason for this level of coupling
 - Common blocks are blocks of shared memory, with every holder of the common stmt having read/write access to anything in the block
 - Large amounts of data are typically shared, often to usurp parameter passing of arrays.

19

Content Coupling

- ❖ The highest form of coupling (worst form)
- ❖ Occurs when one module modifies code and/or data in another module
- ❖ Some re-entrant code from assembly lang. exhibit this form of coupling
- ❖ Can be nearly impossible to detect and debug (because it disappears!)

20

Consider Two Designs

❖ Which has lower coupling?
– Answer: The 2nd design

21

High Cohesion Pattern

- ❖ Formalized by Constantine & Yourdon
– *Structured Design, 1974*
- ❖ Cohesion is the degree to which statements within a module (functions or methods) are inter-related
- ❖ The higher the cohesion, the better
- ❖ Levels of cohesion are identified

22

Levels of Coupling / Cohesion

❖ Data - Low	Best	❖ Informational - High
❖ Stamp		❖ Functional
❖ Control		❖ Sequential
❖ Common		❖ Communication
❖ Content - High		❖ Temporal
		❖ Logical
	Worst	❖ Coincidental - Low

23

Informational Cohesion

- ❖ A concrete realization of Data Abstraction
– classes in C++/Java/other OO langs.
- ❖ The module contains data structure(s) and algorithm(s) which are implemented to provide one concept
– Also known as Abstract Data Types, Packages (Ada), Envelopes (Pascal Plus), Clusters (CLU)
- ❖ Everything works together to provide the abstraction

24

Functional Cohesion

- ❖ Elements within a module are related in performing some mathematical-type function
 - `sin(x)`, `sqrt(x)`, `pow(x, y)`, etc.
- ❖ Functional dependence within a module is a common, sought-after feature

25

Sequential Cohesion

- ❖ Elements are grouped together (in the design of the system) based on data flow
 - Data flow is considered a stronger design issue than control flow!
- ❖ Occurs when the output from one element is input to the next element
 - Examples:
 - ◆ Read next transaction, update master file
 - ◆ “pipes” in Unix, network “sockets”

26

Communication Cohesion

- ❖ Elements refer to the same set of input or output data at the same time in processing
- ❖ Stack operations exhibit this form of cohesion
 - `push()`, `pop()`, `top()`, `new()`, `empty()`
- ❖ Data access is also coordinated in time

27

Temporal Cohesion

- ❖ Group elements together that can all be performed at the same time
- ❖ Initializing variables, initializing the state of an object
- ❖ Temporally cohesive elements tend to also be logically cohesive

28

Logical Cohesion

- ❖ Elements are grouped together because they perform the same logical type of operation
- ❖ Initializing all variables
 - also temporally cohesive
- ❖ Perform all I/O operations
- ❖ Process all records from a file
- ❖ Display error messages

29

Coincidental Cohesion

- ❖ The lowest form of cohesion (worst)
- ❖ Elements within a module have no apparent relationship!
- ❖ Sometimes results when one is forced to upgrade a program to a new language
 - “Modularize” an assembly program into C
 - Convert a functional program to an O-O language (like Java, which only allows member function, no global functions)

30

Coupling & Cohesion

- ❖ Are inversely related
 - as one increases, the other decreases
 - Low coupling, high cohesion is good
 - High coupling, low cohesion is bad
- ❖ Low cohesion means the module should delegate its work to subclasses
 - Just like the person who takes on too much in life, things become complicated & nothing is done well!

31

Controller Expert

- ❖ Assign responsibility of handling system events to a class representing:
 - the overall system (*Facade controller*)
 - the overall business or organization (*Facade controller*)
 - something in the real world that is actively involved in the task (like a person playing a role) (*Role controller*)
 - an artificial handler of all system events of a use case, usually named "<UseCaseName>Handler" (*Use Case controller*)
- ❖ System events are generated by external actors

32

Controller Objects

- ❖ A *controller* is a non-user interface object responsible for handling a system event.
- ❖ A *controller* defines the method for the *System* object
- ❖ POST system events & their operations:

<pre> System endSale() enterItem() makePayment() </pre>	System operations do not have to be fulfilled in the System class. During design, controller classes are often delegated the responsibility for system operations
---	---

33

Who Should be the Controller?

Which class of object should be responsible for handling this system event message?
It is a controller.

- ❖ POST
 - represents the overall "system"
- ❖ Store
 - represents the business organization
- ❖ Cashier
 - represents actor that plays a role in the task
- ❖ BuyItemsHandler
 - represents the handler of the system operation in the use case

34

Controller Choices

35

Answer: It Depends!

- ❖ The same controller should be used for the system events of one use case
 - For instance, *makePayment()* comes after *endSale()*
- ❖ Facade controllers are suitable when there are only a few system events.
- ❖ Only the role controller should be avoided
 - Bloated controllers; poor Design
- ❖ Presentation layer does not handle system events

36
